Problem Set 1

1. Show that $A^T A \neq A A^T$ in general. (Proof and demonstration.)

For a 2x3 matrix A:

```
A <- matrix(c(1,2,3,4,5,6), nrow=2, ncol=3)
A
```

```
## [,1] [,2] [,3]
## [1,] 1 3 5
## [2,] 2 4 6
```

The inverse of this matrix is:

t(A)

```
## [,1] [,2]
## [1,] 1 2
## [2,] 3 4
## [3,] 5 6
```

The product of the inverse of the matrix and the matrix is :

t(A)%*%A

```
## [,1] [,2] [,3]
## [1,] 5 11 17
## [2,] 11 25 39
## [3,] 17 39 61
```

Whereas, the product of the matrix and the inverse is:

A%*%t(A)

```
## [,1] [,2]
## [1,] 35 44
## [2,] 44 56
```

Therefore, $A^T A \neq A A^T$.

2. For a special type of square matrix A, we get $A^TA = AA^T$. Under what conditions could this be true? (Hint: The Identity matrix I is an example of such a matrix).

The conditions under which these are true are for special square matrix. In these instances, the inverse of the matrix is equal to the matrix $A^T = A$. Therefore, if $A^T = A$ then $A^T A = AA^T$.

Such as the matrix:

```
A \leftarrow matrix(c(1,2,3,2,1,2,3,2,1), nrow=3, ncol=3)
Α
##
         [,1] [,2] [,3]
##
   [1,]
             1
                   2
## [2,]
             2
                         2
                   1
             3
                   2
## [3,]
                         1
The inverse of this matrix is:
```

t(A)

```
## [,1] [,2] [,3]
## [1,] 1 2 3
## [2,] 2 1 2
## [3,] 3 2 1
```

The product of the inverse of the matrix and the matrix is:

```
t_AA <- t(A)%*%A
t_AA
```

```
## [,1] [,2] [,3]
## [1,] 14 10 10
## [2,] 10 9 10
## [3,] 10 10 14
```

The product of the matrix and the inverse is:

```
A_At <- A%*%t(A)
A_At
```

```
## [,1] [,2] [,3]
## [1,] 14 10 10
## [2,] 10 9 10
## [3,] 10 10 14
A_At == t_AA
```

```
## [,1] [,2] [,3]
## [1,] TRUE TRUE TRUE
## [2,] TRUE TRUE TRUE
## [3,] TRUE TRUE TRUE
```

Problem Set 2

Matrix factorization is a very important problem. There are supercomputers built just to do matrix factorizations. Every second you are on an airplane, matrices are being factorized. Radars that track flights use a technique called Kalman filtering. At the heart of Kalman Filtering is a Matrix Factorization operation. Kalman Filters are solving linear systems of equations when they track your flight using radars.

Write an R function to factorize a square matrix A into LU or LDU, whichever you prefer.

```
factorization <- function(M){</pre>
  if(nrow(M) == 2){
     if(all(M[, 1] == 0)){
           return(print("cannot solve"))
     while (M[1,1] == 0){
           M \leftarrow M[c(2,1),]
          E21 <- diag(nrow(M))</pre>
          E21[2,1] \leftarrow -M[2,1] / M[1,1]
          U <- E21 %*% M
          L <- solve(U)
          print(U)
         print(L)
      } else {
          if(all(M[, 1] == 0)){
           return(print("cannot solve"))
          while (M[1,1] == 0){
             M \leftarrow M[c(2,3:nrow(M),1),]
          E21 <- diag(nrow(M))</pre>
          E21[2,1] \leftarrow -M[2,1] / M[1,1]
          M2 <- E21 %*% M
          E31 <- diag(nrow(M))
          E31[3,1] \leftarrow -M2[3,1] / M2[1,1]
          M3 <- E31 %*% M2
          E32 <- diag(nrow(M))
          E32[3,2] \leftarrow -M3[3,2] / M3[2,2]
          U <- E32 %*% M3
          L <- solve(E21) %*% solve(E31) %*% solve(E32)
          list(U,L)
          }
A \leftarrow matrix(c(1,2,3,1,1,1,2,0,1),nrow=3)
factorization(A)
## [[1]]
```

```
[,1] [,2] [,3]
##
## [1,]
       1 1 2
## [2,]
       0 -1 -4
## [3,]
        0 0 3
##
## [[2]]
##
     [,1] [,2] [,3]
## [1,]
       1 0
## [2,]
       2
            1
                0
## [3,]
      3
          2
              1
```
